A tensor is a view of [a part of] a storage, which is a low-level 1d vector.

Multiple tensors can share the same storage. It happens when using operations such as view(), expand() or transpose().

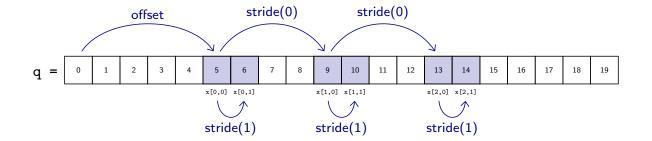

```
>>> y = x.view(2, 2, 2)
>>> y
tensor([[[ 0., 0.],
        [ 0., 0.]],
       [[ 1., 0.],
        [ 0., 0.]]])
>>> y[1, 1, 0] = 7.0
>>> x
tensor([[ 0., 0., 0., 0.],
       [ 1., 0., 7., 0.]])
>>> y.narrow(0, 1, 1).fill_(3.0)
tensor([[[ 3., 3.],
        [3., 3.]])
>>> x
tensor([[ 0., 0., 0., 0.],
       [3., 3., 3., 3.])
```

The first coefficient of a tensor is the one at storage_offset() in storage(). To increment index k by 1, you have to move by stride(k) elements in the storage.

François Fleuret

We can explicitly create different "views" of the same storage

This is in particular how transpositions and broadcasting are implemented.

François Fleuret

This organization explains the following (maybe surprising) error

```
>>> x = torch.empty(100, 100)
>>> x.stride()
(100, 1)
>>> y = x.t()
>>> y.stride()
(1, 100)
>>> y.view(-1)
Traceback (most recent call last):
   File "<stdin>", line 1, in <module>
RuntimeError: invalid argument 2: view size is not compatible with input tensor's size and stride (at least one dimension spans across two contiguous subspaces).
```

x.t() shares x's storage and cannot be "flattened" to 1d.

This can be fixed with contiguous(), which returns a contiguous version of the tensor, making a copy if needed, or with reshape() which combines view() and contiguous().
